## **Health Spending Projections For 2002–2012**

Spending on hospital services and prescription drugs continues to drive health care's share of the economy upward.

## by Stephen Heffler, Sheila Smith, Sean Keehan, M. Kent Clemens, Greg Won, and Mark Zezza

**ABSTRACT:** We forecast a slowdown in national health spending growth in 2002 and 2003, reflecting slower projected Medicare and private personal health spending growth. These factors outweigh higher projected Medicaid spending growth, caused by weak labor markets, and an expectation of continued high private health insurance premium inflation related to the underwriting cycle. Over the entire projection period, national health spending growth is still expected to outpace economic growth. The result is that the health share of gross domestic product is projected to increase from 14.1 percent in 2001 to 17.7 percent in 2012.

ETWEEN 2002 AND 2012 national health spending is projected to grow at an average annual rate of 7.3 percent, reaching \$3.1 trillion by 2012 (Exhibits 1 and 2). This increase would bring health spending to approximately 17.7 percent of gross domestic product (GDP) by 2012, up from its 2001 share of 14.1 percent (Exhibit 3). The shortterm aggregate pattern of national health spending growth is similar to our previous forecast, which showed growth peaking in 2001.<sup>2</sup> After increasing 8.7 percent in 2001, national health spending growth is projected to be 8.6 percent in 2002 and 7.3 percent in 2003. This slowdown would follow five consecutive years of accelerating spending growth.

The overall similarity between our current and previous short-term health spending growth projections masks changes in the composition of growth. First, economywide consumer price inflation for 2002 is projected to be 1.1 percent, well below the 2.3 percent pro-

jected last year. All other things being equal, this would result in a lower projection of health spending growth. However, we project this effect to be partly offset by faster medical price inflation above overall price inflation and more rapid growth in utilization of services.<sup>3</sup>

A second near-term compositional change since our last forecast is a shift toward public spending in 2002 and 2003. Stronger near-term growth in use of care is partially driven by fast growth in Medicaid enrollment, offsetting a decline in private health insurance enrollment (Exhibit 4). The changes in private health insurance and Medicaid enrollment projected for 2002 are related, reflecting higher premiums and softer labor markets. Stronger projected Medicaid enrollment growth produces a Medicaid share of total health spending of 16.7 percent in 2003, compared with 16.1 percent projected last year.

A third revision to projected patterns of growth involves the role of the private health

The authors are all in the Office of the Actuary, Centers for Medicare and Medicaid Services, in Baltimore. Stephen Heffler is deputy director of the National Health Statistics Group. Sheila Smith, Sean Keehan, and Greg Won are economists; Kent Clemens is an actuary; and Mark Zezza is a statistician.

mium growth is projected to accelerate from ll.l percent to ll.6 percent (Exhibit 5).

For 2004 and beyond, the pattern of national health spending growth has been slightly altered, primarily reflecting a higher forecast for real GDP and disposable income

growth.<sup>7</sup> Last year we projected slightly higher national health spending growth in 2004 followed by a period of nearly continuous deceleration. This year our forecast shows an extended period of modest acceleration in growth until 2007, and then a more gradual

slowing to a 2011 growth rate that is similar to last year's forecast (6.8 percent this year versus 6.7 percent last year). This pattern of growth, together with revised historical GDP data, results in a projected national health spending share of GDP that is only slightly higher than we forecasted last year. We now expect national health spending to equal about 17.4 percent of GDP in 2011, compared with last year's forecast of 17.0 percent.

The national health spending projections are generated within a framework that incorporates actuarial, econometric, and judgmen-

tal inputs. "Current law" projections for Medicare are based on the 2002 Medicare Trustees Report; Medicaid spending projections are consistent with Trustees Report assumptions. Projections for private health spending are based on an econometric model. Both the private and public projections use the economic and demographic assumptions from the 2002 Medicare Trustees Report, updated to reflect the latest historical data. Our projections are conditional on assumptions about macroeconomic conditions and health sector parameters, with the degree of uncertainty in-

creasing with the projection horizon. We qualify our projections, then, subject to these inherent uncertainties and how they might affect our results.

### **The Funding Outlook**

■ Private-sector spending. Last year we expected that private personal health care spending growth would peak in 2002, but the latest outlook indicates that the peak actually occurred in 2001. After increasing 7.9 percent in 2001, private personal health care spending growth is now projected to fall to 7.4 percent in 2002 and eventually decline to 6.1 percent in 2012. We ascribe much of the long-term deceleration to slowing real per capita income growth, an increase in the uninsured population, and increased consumer cost sharing.

In the near term the forecast revision reflects three major factors. First, the Commerce Department's Bureau of Economic Analysis (BEA) released downward revisions to historical disposable personal income. Since changes in income have a lagged effect in our models, the BEA revisions result in lower projected near-term health spending growth. Second, the Labor Department's Bureau of Labor Statistics (BLS) health-sector payroll data for the first ten months of 2002 show a deceleration in growth relative to 2001, suggesting, all other things held constant, a slowing in health ex-

penditure growth.<sup>13</sup> Third, published BLS data for 2002 indicate slower medical price growth than was projected last year.<sup>14</sup>

An important influence on our private health spending projections is overall economic growth as measured by a moving average of growth in real per capita disposable personal income. This variable has been included in our model since the inception of the current projections methodology in 1998. The lagged income effect on health spending is a function of the role of third-party payers, which largely insulate health expenditures from simultaneous changes in household income. Since consumers generally do not pay for most of their medical expenses directly, their purchasing decisions are not immediately affected by short-term variations in income. Thus, the effects of income not only reflect the direct impact of consumers' choice of medical care but also are intended to indirectly capture a large range of structural changes in the financing and delivery of care, which occur in response to changes in economic growth.

One example of such an effect was the introduction and spread of managed care in the mid-1990s, which was partly a lagged response to rapid increases in health spending relative to income in the early part of that decade. Similarly, the recent greater willingness to pay for medical care—evidenced by a shift toward less

W3-58 7 February 2003

restrictive forms of coverage, the passage of a range of patient protection laws at the state and federal levels, and the passage of legislation more generous to providers—can be seen as a response to rising real income growth in the mid- to late 1990s.

In response to the recent economic slowdown, employers have raised employee costsharing requirements, both as a condition of coverage and at the point of service. 15 Also, prescription drug plans are making greater use of tiered copayments as a tool to manage demand. Other responses include the introduction of new disease management programs for the chronically ill, retrenchment in coverage of retirees and part-time employees, legislation to curb malpractice awards, and the introduction of defined-contribution employer health plans. 16 Although future structural changes are difficult to predict, our projections suggest that over time consumers and employers will act through a range of channels to restrain costs as income growth slows.

Enrollment growth peaked in 2000 as a result of stiff competition for workers and because of employers' reluctance to pass premium increases on to employees. Last year we projected a deceleration in private health insurance enrollment growth in 2001 because of the recession (although forecasted enrollment growth was still positive), followed by a slight acceleration in anticipation of a modest economic recovery. In fact, enrollment actually declined sharply in 2001, largely because of weaker-than-expected employment growth and, to a lesser degree, double-digit premium increases.<sup>17</sup>

The projected trend in private health insurance enrollment reflects cyclical and long-term factors. In the near term we expect that enrollment will continue to decline in 2002, reflecting the weak economy and continued premium inflation. As in 2001, changes in employment patterns by sector in 2002 (through November) suggest a decline in the privately insured population.

We expect enrollment growth to turn positive in 2003 and peak in 2005, as economic

growth accelerates and the underwriting cycle enters a downward phase. However, we expect private enrollment as a fraction of the total population to fall throughout the projection period, as health care costs grow faster than incomes, as the composition of employment shifts to industries that tend to have less coverage, and as the Medicare-eligible share of the population rises.<sup>18</sup>

The underwriting cycle. Historically, the net cost of insurance as a share of total private health insurance follows a cyclical path. Price competition during a "soft market" leads to shrinking margins and, concomitantly, company insolvencies. This, in turn, results in a "hard market" characterized by reduced competitive pressures, rising premiums, and more stable profits. Hard markets have been typically short-lived, with the net cost ratio falling sharply after a peak. The data also show that the amplitude of the cycles dampened in the 1990s, relative to 1970–1990, coincident with the shift in enrollment to managed care plans.

Our forecast suggests two changes to the recent historical pattern. First, we project a rise in 2002 for the net cost of insurance as a share of premiums to 14 percent, which is higher than any period in the 1990s but lower than the hard markets observed in the premanaged care period. Our projection for 2002 shows a slowing in the rate of benefit growth, lower projected private health insurance enrollment, increasing profits for many of the larger health insurers, and accelerating premium growth.<sup>20</sup>

Second, we expect this hard market to exhibit a more gradual softening than has historically been the case. More generally, we anticipate a much weaker underwriting cycle in the future, reflecting anecdotal evidence of reduced competition (with fewer small insurers present, as a result of industry consolidation) and more savvy management that is less likely to overreact to cyclical swings (especially during hard markets).

We expect that out-of-pocket spending will continue to grow more rapidly in the projection period than in the managed care period (1993–1997) because of efforts by employers

and insurers to share costs with employees. At the same time, the growth rate of total health spending is expected to be higher than that of out-of-pocket spending. Hence, the out-of-pocket share of total health expenditures is projected to fall 1.2 percentage points, from 14.1 percent in 2002 to 12.9 percent in 2012. By way of comparison, this share fell 4.2 percentage points between 1991 and 2001 and 4.0 percentage points between 1980 and 1990.

■ Public-sector spending. Public health

care spending growth accelerated sharply in 2001, increasing 9.4 percent compared with 7.5 percent in 2000 (Exhibit 6). This growth was primarily attributable to large Medicaid enrollment growth and increased Medicare payments to providers, reflecting provisions introduced under the Medicare, Medicaid, and SCHIP Balanced Budget Refinement Act (BBRA) of 1999 and the Medicare, Medicaid, and SCHIP Benefits Improvement and Protection Act (BIPA) of 2000. Based on current law,

<sup>&</sup>lt;sup>c</sup>Includes Medicaid and SCHIP expansion (Title XXI).

we project that Medicare spending growth will slow in 2002 (5.2 percent) and 2003 (3.0 percent) because of the expiration of many of the provisions of the BBRA and BIPA, and reduced reimbursement per service for physicians under the sustainable growth rate (SGR) system. Because of this system and its cumulative nature, physician reimbursement per service is projected to decrease from 2002 to 2006. This pattern of physician spending differs from last year's projection; the change comes primarily from BEA revisions to the historical GDP, revisions to projected economic data, and updates to the Medicare data that track physician spending. The negative physician updates have attracted the attention of Congress, but as yet no legislation has been passed to alter the outlook. In the later part of the forecast, Medicare is projected to return to higher levels of growth, reaching 7.4 percent in 2012.

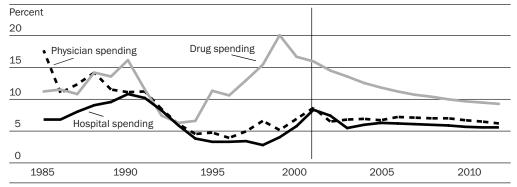

Medicaid spending also accelerated in 2001, growing at 10.8 percent. We project that this acceleration will continue into 2002, to 12.1 percent. High Medicaid spending growth is largely attributable to an 8.5 percent increase in enrollment in 2001 and a 5.8 percent increase in 2002 caused by the slowdown in economic growth. After 2002, Medicaid spending growth is expected to remain strong but to slow to 8.5 percent by 2012.

### The Outlook For Health Services Spending

Recent historical trends in the major sectors are expected to continue in the near-term projection period. Our projections for 2002 suggest that hospital spending growth, driven by higher hospital labor costs and increased hospital leverage in pricing, will remain the most important driver of health spending growth. Hospital spending accounts for 27.1 percent of the projected increase in health spending in 2002, while prescription drug spending and physician spending account for 16.3 percent and 16.5 percent, respectively. Spending on drugs, the fastest-growing sector, is expected to continue its recent deceleration, in part because of the increasingly broad use of tiered copayments and fewer new drug introductions. For physicians, current-law Medicare payment updates under the SGR system are projected to slow total physician spending growth.

■ Hospitals. Hospital spending growth accelerated sharply in 2001, to 8.3 percent (from 5.8 percent growth in 2000), and is projected to slow slightly to 7.4 percent in 2002 (Exhibit 7). The near-term pattern of growth is largely attributable to Medicare hospital spending, which grew 7.2 percent in 2001 but is projected to decelerate to 5.7 percent in 2002 and 2.9 percent in 2003. The dominant influ-

EXHIBIT 7
Percentage Change In Spending For Hospital Care, Prescription Drugs, And Physician Services, 1985–2012

SOURCE: Centers for Medicare and Medicaid Services, Office of the Actuary.

NOTE: Vertical line denotes beginning of projections; trend lines to the left of the vertical line represent historical data.

ence on this pattern of growth has been the effects of the Balanced Budget Act (BBA) of 1997 and subsequent legislation (the BBRA and BIPA) that softened its impact. Key changes projected for hospitals in 2002 and 2003 are concentrated in hospital-based home health and skilled nursing facilities (SNFs). In contrast, acceleration in Medicaid hospital spending largely reflects current and projected rapid growth in enrollment propelled by rising unemployment. After increasing 10.2 percent in

2001, Medicaid hospital spending is projected to grow 11.9 percent in 2002.

Private spending growth for hospital services has been accelerating consistently since its trough of -1.0 percent in 1994. Growth was 7.8 percent in 2001, and similar rates of growth are expected

in both 2002 and 2003. The recent acceleration in hospital spending per enrollee by private health insurance has been quite rapid (with growth increasing from 6.3 percent in 2000 to 9.9 in 2001) and reflects the consolidation of hospitals in many local markets and a trend toward less restrictive networks of providers. Per enrollee hospital spending growth is projected to ease to 8.2 percent in 2002 and 8.0 percent in 2003.

The recent acceleration has been particularly rapid for inpatient hospital spending, narrowing the difference between inpatient and outpatient spending growth. Community hospital outpatient spending grew 7.2 percentage points faster than inpatient spending in 1995, but just 3.1 percentage points faster in 2000.<sup>21</sup> We project a continued convergence of inpatient and outpatient spending growth rates, so that by 2012 outpatient spending grows just 1.1 percentage points faster than inpatient spending.

We project private hospital spending growth to slow from 7.7 percent in 2003 to 5.0 percent in 2012, reflecting a growing acceptance of more restrictive forms of coverage. In our model, the restrictiveness of managed care is represented by the share of the privately in-

sured population enrolled in health maintenance organizations (HMOs), which is used as a proxy for the effects of all mechanisms of managing care.<sup>22</sup> Recent research continues to confirm HMOs' cost-restraining influence on hospital use and spending growth.<sup>23</sup> The decline in HMO enrollment between 1999 and 2001, and the associated shift toward looser forms of managed care, is believed to have played a role in accelerating utilization per capita and hospital price inflation for this pe-

riod. In the long run, we project that a slowing economy will resurrect pressures—captured in part by the HMO proxy—to restrain hospital spending growth.

■ **Prescription drugs.** Similar to last year, our drug spending projections show a continued deceleration in the

rate of growth, moving from 15.7 percent for 2001 to 14.3 percent in 2002 and reaching 9.2 percent by 2012. The turning point for prescription drug spending growth came in 1999, preceding the projected peak for total national health spending growth by two years. The deceleration in growth has been caused primarily by the introduction of tiered-payment schemes and fewer recent "blockbuster" drug introductions, and it is expected to continue as a result of the expansion of these schemes and the introduction of other forms of cost sharing.

We project that drug spending growth will increase at an average annual rate of 11.1 percent between 2002 and 2012, which exceeds total health spending by 3.8 percentage points per year, on average. By 2012 we project that prescription drug expenditures will account for 14.5 percent of total health expenditures; in 2001 the share was 9.9 percent.

The projected growth path of drug spending is influenced by a number of factors, including real disposable personal income, drug prices relative to overall consumer prices, direct-to-consumer (DTC) advertising, and new drug introductions.<sup>24</sup> The impact of higher drug prices will be the strongest be-

W3-62 7 February 2003

"In the long run, we

project that a

slowing economy will

resurrect pressures

to restrain hospital

spending growth."

tween 2002 and 2004, when drug price growth is projected to be 3.2 percentage points per year greater, on average, than overall consumer prices. For 2005 through 2012 we project the difference between drug and overall price growth to average 1.6 percentage points per year. Spending for DTC advertising grew at an average annual rate of 44.9 percent from 1995 through 2000.<sup>25</sup> However, in 2001 it grew at only 9.4 percent and is expected to decelerate throughout the projection period. New drug introductions are expected to grow steadily but at a slower rate than we anticipated last year, as Food and Drug Administration (FDA) approval times have increased and the number of new drug applications has fallen below expectations.<sup>26</sup>

There are a number of important factors affecting these prescription drug projections. Studies have shown that use of prescription drugs has been rising recently because of an increased number of people affected by chronic conditions and because of doctors' prescribing more drugs per office visit.<sup>27</sup> The result is that use is increasing for all age groups. In addition, the expansion of state prescription drug programs could further increase public spending for prescription drugs. However, patents for several blockbuster drugs are scheduled to expire during the projection period. If the majority of the users of these drugs switch to the less expensive generic alternative, spending in those therapeutic classes may fall. Also, three-tier drug plans have shifted more costs to consumers and encouraged the use of generic drugs and brandname drugs on the formulary. Since insurance companies succeeded in slowing use after implementing these plans, some may try other forms of cost sharing, such as substantially raising the copayment for brand-name drugs (the third tier) or creating four- or five-tier drug plans. While many of the factors likely to influence prescription drug spending over the next decade work in opposite directions, our projections implicitly attempt to take these forces into account.

■ Physician and clinical services. Historically, spending for physician and clinical

services has grown at a rate roughly similar to that of total health spending, and the same pattern is expected to occur during the forecast period. The average annual growth between 2002 and 2012 is projected to be 6.8 percent for physician services, relative to the corresponding 7.3 percent growth for total health spending.

For 2002 through 2005 this year's forecast of the growth in physician spending is much slower than last year's was. Medicare physician spending growth is low in the beginning of the forecast period because of the SGR system, which ties physician spending to economic growth. Slower private physician spending for the near term is mainly the result of slower disposable personal income growth in the recent historical period. For 2005 through 2012 we project physician spending growth to accelerate faster in this year's projections than in last year's, primarily because of higher projected disposable personal income growth. The continued shift of care to other professional services, negative updates to the Medicare physician payment rates, and faster growth in other sectors such as prescription drugs are all expected to contribute to the slow continued decline in physician spending as a share of total health care spending.

Quite a bit of uncertainty exists surrounding the factors that might influence physician spending. It is unclear how the trends in prescription drug spending will affect the number of physician office visits. The implementation of consumer-driven health care tools (such as tiered plans, concierge service, information access and delivery tools available through the Web, and portable and self-administered medical devices) that are aimed at providing better-value, more efficient health care may have strong influences on physician spending. In the past, changes in how health care services are distributed typically emanated from pressure being applied by third-party payers, such as managed care organizations and government. The need to constrain and reduce health care costs often motivated their efforts. It is not clear whether consumers, with an increased role in the distribution of health care services, will have the same motivation and impact.<sup>28</sup>

Both the recently released historical health spending estimates and this set of projections have highlighted the enormous pressures mounting on our health care system. Private health insurance premiums are rising at rapid rates, federal and state budget shortfalls exist, a softer labor market has reduced the number of people with private insurance and has increased Medicaid enrollment, and provider costs are continuing to rise. These trends have the unique, although not unparalleled, impact of affecting all of the relevant parties—from payers to providers to employers to consumers—at the same time.

Experience indicates that changes in the mechanisms of payment and delivery of care, as well as consumers' preferences and public sentiment, will result in a slowdown in growth, temporarily alleviating some of these pressures. However, experience also indicates that society is likely to be willing to allocate more of each dollar of income to health care. We project both of these outcomes over the next decade: national health spending growth slowing from 8.7 percent in 2001 to 6.7 percent in 2012, and the share of GDP accounted for by health care increasing from 14.1 percent in 2001 to 17.7 percent in 2012. The intriguing part of the next decade may be where it leaves us, since the baby-boom generation will begin to become eligible for Medicare at the end of the projection period, and an unparalleled set of pressures on the system is likely to develop.

The authors thank Dirk Hoffman, Mary Lee Seifert, and Art Sensenig for their assistance in producing these projections. They also thank Cathy Cowan, Cathy Curtis, Rick Foster, Mark Freeland, Katie Levit, John Poisal, and anonymous peer reviewers for their helpful comments. The opinions expressed here are the authors' and do not necessarily represent those of the Centers for Medicare and Medicaid Services.
